The AIR LIQUIDE's direct and indirect emissions of greenhouse gases (GHG) in 2016

The Group's direct and indirect emissions of greenhouse gases (GHG) in 2016

25
million tons
of CO₂

Producing and transforming while releasing less CO2

PRODUCING OUR SMALL MOLECULES MORE EFFICIENTLY OXYGEN, WITH LESS ELECTRICITY

Constant innovation within the technologies reduces the use of electricity by our ASUs by about 12% in the last fifteen years.

HYDROGEN, WITH LESS NATURAL GAS (SMR-X)

The significant improvement in SMR technologies took shape in 2012 in the SMR-X in Antwerp, Belgium, enabling the production of hydrogen without the simultaneous production of steam. It reduces the amount of natural gas required by 5% compared with the technology without the economic valorisation of steam. This represents 20,000 tons of CO2 avoided per year.

CO₂ : Where is the imbalance coming from?

Today, **natural gas, coal, and oil** provide energy for industrial processes and thus generate about **20% of global emissions**.

For CO₂ neutral glass production by 2030 ambition, some Energy transition scenarios are to be investigated

- Full electrical and hybrid furnace designs (oxy-firing)
- Co-Firing of Biogas or Hydrogen
- Carbon capture, valorization and heat recovery

Four major levers to decarbonize the energy system

Final energy consumption EJ

AL solutions contribution for glass industry

1 - Increasing energy efficiency
Limits the rise of energy consumption

Oxy-combustion + recovery
Heat Oxy Combustion...
From 20 to 50 % fuel saving

2 - Fossil fuels - CCS/U

CO2 capture technologies
Absorption, Adsorption, cryogenic, membranes.

3 - Switch to zero emission energy carriers, e.g. electricity or Hydrogen

Hydrogen energy
SMR, Methanol cracker, electrolyse

4 - Renewables
Replace fossil fuels

Biomass and waste
Digestor, pyrolyse....

3

Driving performance to the next level

Oxy-firing

Without additional energy recovery measures, the average energy saving will be :

- In recuperative furnaces about 25 – 35 %, including the energy consumption for oxygen production.
- For large regenerative furnaces this value is in the range of 0–15%.

It can be said that from oxy-fuel melting : the reduced emissions will significantly outweigh the emissions associated with the oxygen production.

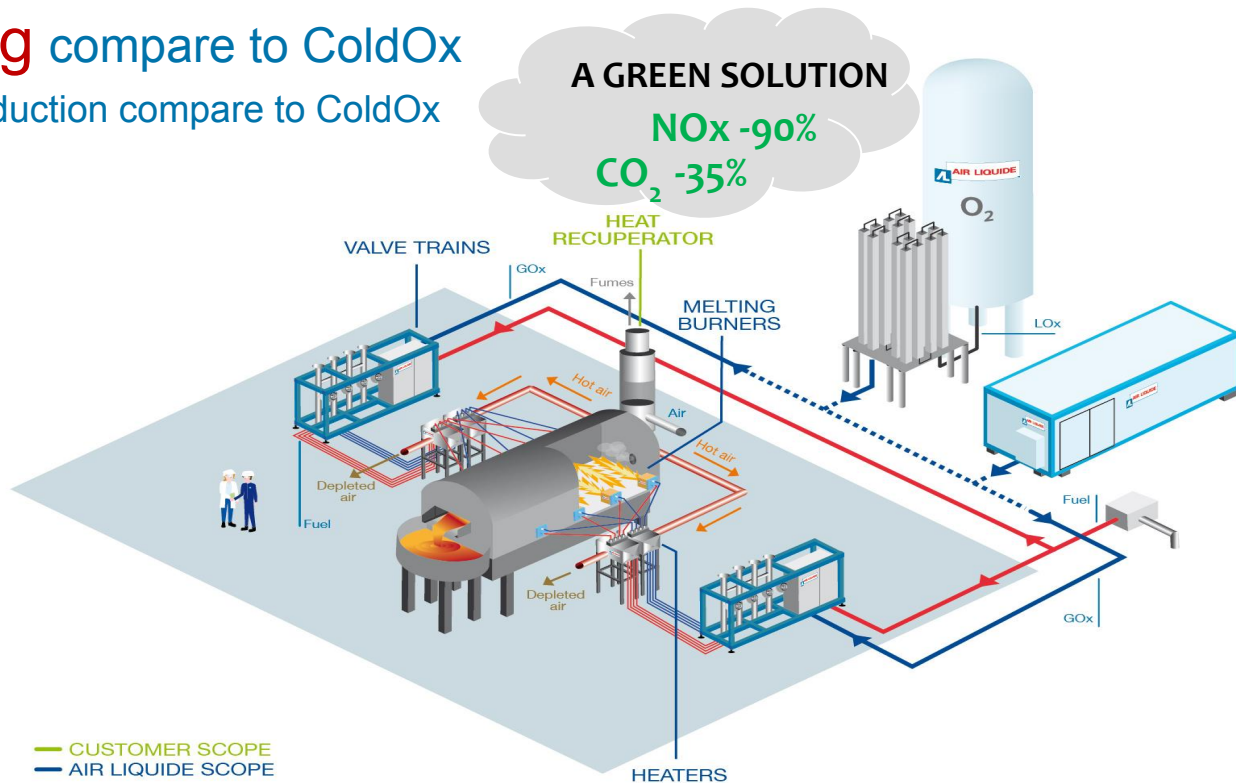

The Next Generation Oxy Combustion Technology

Fuel **more 10% saving** compare to ColdOx

- CO₂ (from combustion) 10% reduction compare to ColdOx
- NO_x reduction

A COMPETITIVE SOLUTION ...

Mixing advantage of oxy-fuel and heat recovery

3 references with proven results

Float glass

Boussois (France) in 2009 &
Retenize (CZ) in 2014 - 600TPD

Energy savings =

- - **25% vs Air combustion**

- CO2 emissions from combustion=
- **25% vs Air**

- NOx emissions from combustion =
- **83% vs Air**

Tableware

Trakya **Glass** (Bulgaria) in 2016 -
200TPD

- Energy savings objectives =
- **20% vs Air combustion**

- CO2 emissions from combustion=
- **20% vs Air**

- NOx emissions from combustion=
- **90% vs Air**

Energy cost variation

Natural gas and Crude oil still low.

On an average, the energy costs in the glass industry accounts for about 14% of the total glass production costs.

In the context where energy is decreasing, CAPEX of heat recovery system would have to be reduced proportionally.

AL's portfolio of CO₂ capture technologies

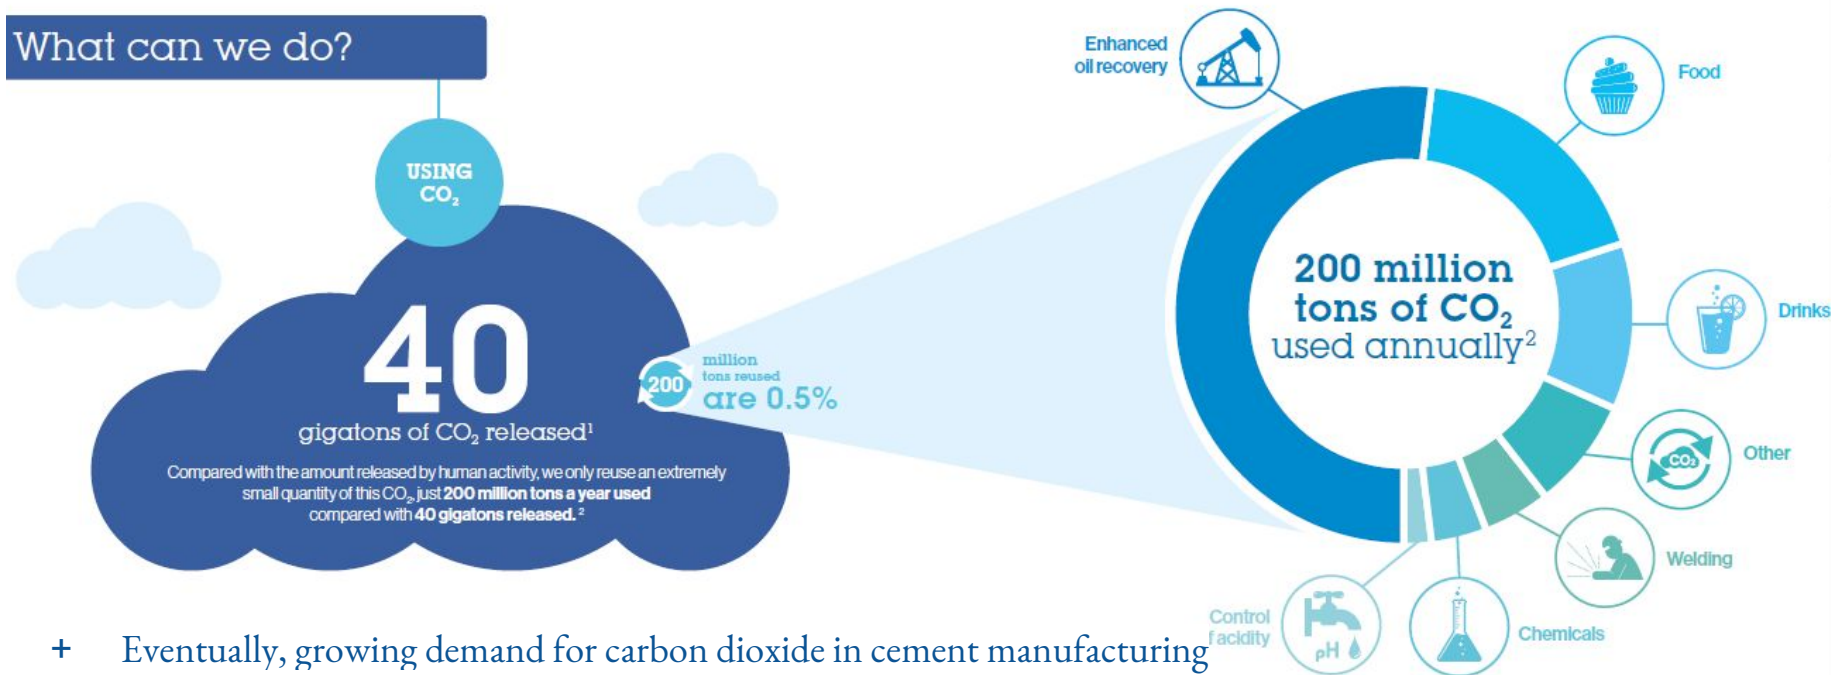

CRYOCAP™: A line of products for CO2 capture

Air Liquide Global E&C Solutions has developed a range of CPU (Cryogenic Purification Units) dedicated to CO2 capture:

CO2 capture from H2 production plants (SMR / Refineries)	CRYOCAP™ H2
CO2 capture from oxy-combustion flue gas	CRYOCAP™ Oxy
CO2 capture from blast furnaces	CRYOCAP™ Steel
CO2 capture from CO2 rich Natural Gas (> 30%)	CRYOCAP™ NG

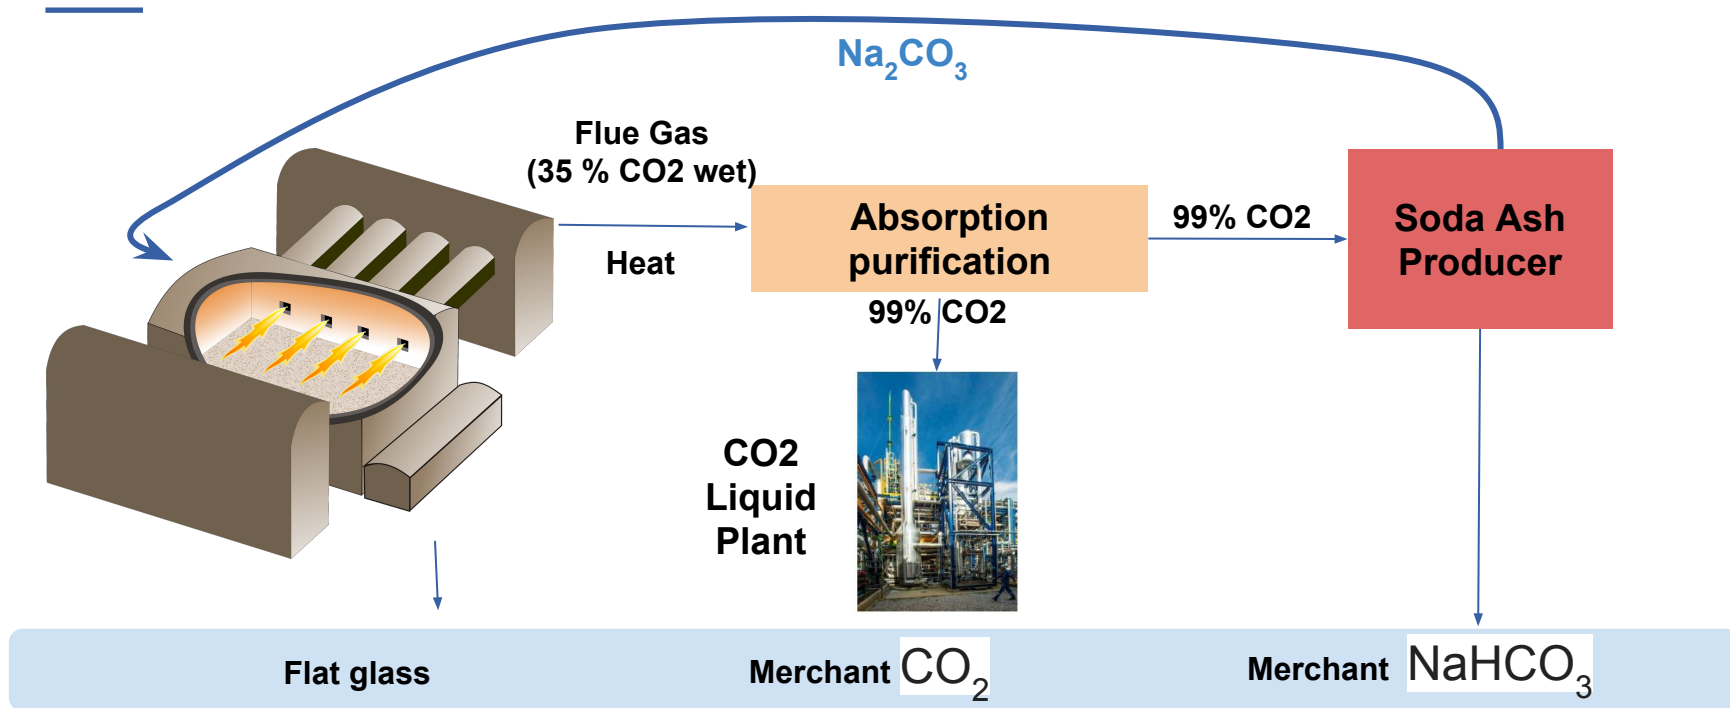

CO2 reuse?

What can we do?

- + Eventually, growing demand for carbon dioxide in cement manufacturing and in making plastics and other carbon-based materials.

Large Float Furnace - Oxy Combustion Case

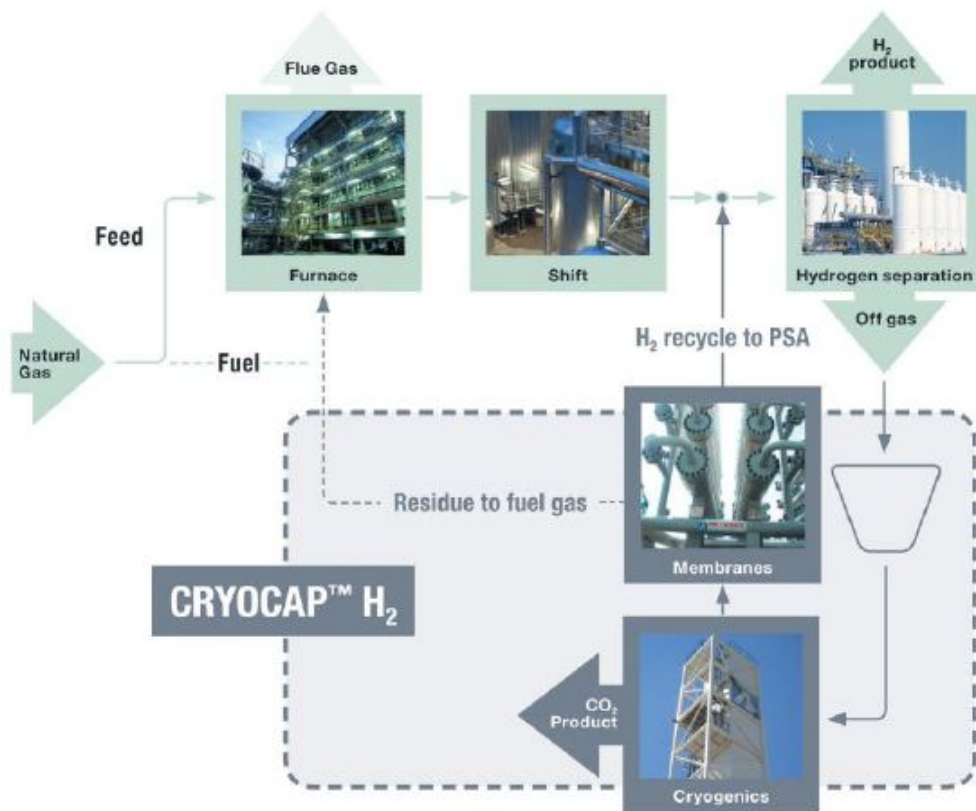

CRYOCAP™ H2 Port Jérôme - Key facts

- **First reference at industrial scale at Port Jérôme, Normandie, France**
 - Plant built, owned & operated by Air Liquide group
 - Start up in H1 2015
- **CRYOCAP figures:**
 - Existing SMR : 50 000 Nm³/h H₂ production
 - PSA off gas treated: 17 000 m³/h
 - Liquid CO₂ production: 300 tons/day
 - Food Grade CO₂
- **Successful operation**
 - Performance: CO₂ purity and recovery achieved
 - Stable industrial operation
 - H₂ production: +2800 Nm³/h, i.e. ≈ +5% (only partial flow treated)
 - Plant efficiency increased by 2%

CRYOCAP™ H2 = the lowest cost of capture for SMR

Key features:

- Combination of cryogenics and membranes technologies
- Extra H₂ production: by 10 to 20%
- CO₂ capture rate: 98% CO₂ from syngas
- Cost reduction: -30% to -40% compared to aMDEA

Hydrogen mode of supply

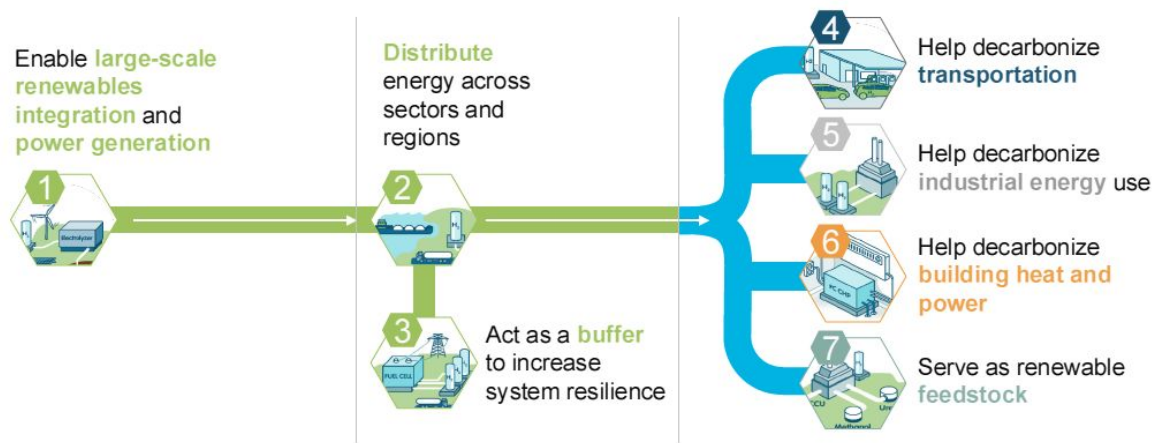

- Hydrogen has been almost entirely (99%) used as feedstock for industrial applications
- The use of hydrogen as an energy carrier is beginning to accelerate

Zero-emission hydrogen

Today, 99% of hydrogen is produced through fossil fuel reforming

Pathways to produce zero-emission hydrogen:

- Steam methane reforming (SMR), using bio-methane , or combined with CCS/U
- Electrolysis using electricity generated by renewables
- Gasification of biomass

Hydrogen empowers the energy transition

Hydrogen offers a viable solution:

Direct **electrification** is **technologically challenging or uneconomical** like for energy-intensive industries.

High-grade heat - above 400°C - is harder to decarbonize. **Hydrogen burners can complement electric** heating.

Fuel cells have a higher efficiency than burners but their deployment still requires significant investment.

Burners require only adjustments of existing equipment.

Oxy-hydrogen flame features

The O₂/H₂ flame:

Water

- Produces essentially water
- Stoichiometric ratio the best deflagration speed = **10,7m/s**
- High adiabatic temperature = **3080°C**
- produced a reddish-orange flame due to the strong emission band of H₂O at 632 nm

The oxy-hydrogen flame radiates the major part of its energy in wavelengths above **2.4 μm**.

- The radiant energy above 2.4 μm is absorbed at the glass surface
- Favors solely a surface heating

Emissivity

Does oxy-hydrogen flames suit for glass melting

- Polishing with oxy-hydrogen flames creates a limited remelting of the glass surface. The oxy-hydrogen flame is well adapted to this operation.
- For melting, full Oxy-Hydrogen flame will :
 - Increase of water content changes Redox of the combustion atmosphere as well as for the glass
 - Heat transfer due to flame emissivity different from fossil fuel combustion
 - Flame shape control and burners design must be adapted

Biomass

Air Liquide has developed technologies and know-how that span the entire biomethane or natural gas value chain:

the purification of biogas into biomethane, liquefaction, packaging, and the injection of biomethane into the natural gas grid for clean transportation.
